- 概率是度量随机事件发生的可能性的方法

- 概率论是研究随机现象规律的一门学科

实际场景

- 基本概念

掷骰子

- 随机试验： E

- ✓可重复性：试验在相同条件下可重复进行

- ✓可知性：每次试验的可能结果不止一个，并且事先能明确试验所有可能的结果

- ✓不确定性：进行一次试验之前不能确定哪一个结果会出现，但必然会出现结果中的一个

- 样本空间： Ω

- ✓随机试验 E 的所有可能出现的基本结果组成的集合

- 事件： A

- ✓满足某些条件的样本点所组成的集合，是样本空间的子集，即 $A \subseteq \Omega$

- E 是一随机试验, Ω 是其上的样本空间, 对于 E 上的事件 A , 定义函数 $P(\quad)$ 。称 $P(\quad)$ 为随机试验 E 上的概率, 如果函数 $P(\quad)$ 满足以下三个条件
 - 非负性: $\forall A \subseteq \Omega, 0 \leq P(A) \leq 1$
 - 规范性: $P(\Omega) = 1$
 - 可列可加性: 对可列事件 $A_1, A_2, \dots$, 如果其中任意两个事件互不相容 (即 $A_i \cap A_j = \emptyset, i \neq j$) , 有

$$P\left(\bigcup_{i=1}^{\infty} A_i\right) = \sum_{i=1}^{\infty} P(A_i)$$

- $P(\emptyset) = 0$
- 两两互不相容的 N 个事件 $A_1, A_2, \dots, A_N$, 有 $P(\bigcup_{n=1}^N A_n) = \sum_{n=1}^N P(A_n)$
- $\forall A \subseteq \Omega$, 记 $A^c = \Omega - A$, 有 $P(A^c) = 1 - P(A)$
- 当 $A \subseteq B$, 有 $P(B - A) = P(B) - P(A)$
- 任意 A, B , 有 $P(A \cap B) = P(B) - P(B - A)$, 简记 $P(A \cap B)$ 为 $P(A, B)$ 或 $P(AB)$
- 任意 A, B , 有 $P(A \cup B) = P(A) + P(B) - P(A \cap B)$
- 任意 $A_1, A_2, \dots, A_N$, 有

$$P\left(\bigcup_{i=1}^N A_i\right) = \sum_i P(A_i) - \sum_{i < j} P(A_i, A_j) + \sum_{i < j < k} P(A_i, A_j, A_k) + \dots + (-1)^{N+1} P(A_i, A_j, \dots, A_N)$$

- 给定事件 A , 事件 B 发生的条件概率定义如下

– 注意: $P(A) > 0$, 否则没定义 $P(B|A) \triangleq \frac{P(A, B)}{P(A)}$

- 联合概率

$$P(A, B) = P(A)P(B|A) = P(B)P(A|B)$$

- 全概率公式

– $A_1, A_2, \dots, A_N$ 两两互不相容, 且 $\bigcup_{n=1}^N A_n = \Omega$

$$P(B) = \sum_{n=1}^N P(A_n, B) = \sum_{n=1}^N P(A_n)P(B|A_n)$$

- 乘法公式

$$P(A_1, A_2, \dots, A_N) = P(A_1)P(A_2|A_1) \cdots P(A_N|A_1, A_2, \dots, A_{N-1})$$

- 给定事件 A 和 B ，称 A 和 B 是独立的，如果

$$- P(A, B) = P(A)P(B)$$

- 称事件 $A_1, A_2, \dots, A_N$ 是独立的，如果对任意的 $A_{s_1}, A_{s_2}, \dots, A_{s_k} (k \leq N)$ ，有

$$- P(A_{s_1}, A_{s_2}, \dots, A_{s_k}) = \prod_{i=1}^k P(A_{s_i})$$

- 给定事件 C ，称事件 A 和 B 在事件 C 下是条件独立的，如果

$$- P(A, B|C) = P(A|C)P(B|C)$$

- 给定事件 C ，称事件 $A_1, A_2, \dots, A_N$ 在事件 C 下是条件独立的，如果对任意的 $A_{s_1}, A_{s_2}, \dots, A_{s_k} (k \leq N)$ ，有

$$- P(A_{s_1}, A_{s_2}, \dots, A_{s_k}|C) = \prod_{i=1}^k P(A_{s_i}|C)$$

- 在实际应用中，人们常常对结果的某些函数更感兴趣，而不是对于试验结果本身。
 - 如在掷骰子时，以两次骰子的点数和定输赢。这时，我们关心两次结果的和，而非具体的试验结果。比如，我们关系点数和是否为9，而并不关心其实际结果是否是 $(3, 6)$ 、 $(4, 5)$ 、 $(5, 4)$ 、 $(6, 3)$ 。
- 这些定义在样本空间上的实值函数（我们关注的内容），称为随机变量 (random variable)
 - X 表示随机变量
 - $\mathcal{X}$ 表示随机变量的取值空间，也称样本空间
- 两类随机变量
 - 离散随机变量 (discrete random variables)
 - 连续随机变量 (discrete random variables)

- 离散随机变量
 - 样本空间 $\mathcal{X}$ 包含有限个或可数个元素
- 概率质量函数 (probability mass function, pmf)
 - $p(x) \triangleq P(X = x)$
 - 性质
 - ✓ $0 \leq p(x) \leq 1$
 - ✓ $\sum_{x \in \mathcal{X}} p(x) = 1$
- 以掷骰子（假定均匀）为例
 - X : 掷两次骰子的点数之和
 - $\mathcal{X} = \{2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12\}$
 - $p(9) = P(X = 9) = P((3,6), (4,5), (5,4), (6,3)) = \frac{4}{36}$

- 连续随机变量 (discrete random variables)
 - 样本空间 $\mathcal{X} = \mathbb{R}$, 即 $x \in \mathbb{R}$
- 累积分布函数 (cumulative distribution function, cdf)
 - $P(x) \triangleq P(X \leq x)$: 单调上升
 - 事件 $A = (X \leq a), B = (X \leq b), C = (b < X \leq a)$: $P(A) = P(B) + P(C)$
- 概率密度函数 (probability density function, pdf)
 - $p(x) \triangleq \frac{d}{dx}P(x)$
 - 例子

$$P(a) = P(A) = \int_{-\infty}^a p(x)dx \quad P(C) = \int_b^a p(x)dx$$

- 之前关注一个随机变量上的概率分布
- 联合概率分布简称联合分布，是两个及以上随机变量组成的随机向量的概率分布
- 根据随机变量的不同，联合概率分布的表示形式也不同。
 - 对于离散型随机变量，联合概率分布可以以列表的形式表示，也可以以函数的形式表示
 - 对于连续型随机变量，联合概率分布通过一非负函数的积分表示

$$\mathbb{V}[X_i] = \text{Cov}[X_i, X_i]$$

$$\text{Cov}[\mathbf{X}] \triangleq \mathbb{E}[(\mathbf{X} - \mathbb{E}[\mathbf{X}])(\mathbf{X} - \mathbb{E}[\mathbf{X}])^T]$$

$$= \mathbb{E}[(\mathbf{X} - \boldsymbol{\mu})(\mathbf{X} - \boldsymbol{\mu})^T]$$

$$= \mathbb{E}[\mathbf{X}\mathbf{X}^T] - \boldsymbol{\mu}\boldsymbol{\mu}^T$$

不相关不代表独立

如果随机变量 X_i 和 X_j 独立, 则 $\rho_{ij} = 0$ 。这时也称 X_i 和 X_j 不相关

注意：随机变量 X_i 和 X_j 不相关, 推不出 X_i 和 X_j 独立

例如： X_i 是区间 $[-1, 1]$ 上的均匀分布, 即 $X_i \sim U(-1, 1)$, $X_j = X_i^2$ 。
显然, X_i 和 X_j 不独立

$$\begin{aligned}\text{Cov}[X_i, X_j] &= \mathbb{E}[X_i X_j] - \mathbb{E}[X_i] \mathbb{E}[X_j] \\ &= \mathbb{E}[X_i^3] - \mathbb{E}[X_i] \mathbb{E}[X_i^2] \\ &= 0 - 0 \mathbb{E}[X_i^2] = 0\end{aligned}$$

假定统计样本为10000人

感染人数为 $10000 \times 0.1 = 1000$ 人

感染的人中有 $0.9 \times 1000 = 900$ 人检测呈阳性

未感染的9000人中有 $0.05 \times 9000 = 450$ 人检测呈阳性

故检测呈阳性的人数为 $900 + 450 = 1350$

故
$$P(H = 1|X = 1) = \frac{900}{1350} = 0.667$$

感染人数为 $10000 \times 0.02 = 200$ 人

感染的人中有 $0.9 \times 200 = 180$ 人检测呈阳性

未感染的9800人中有 $0.05 \times 9800 = 490$ 人检测呈阳性

故检测呈阳性的人数为 $180 + 490 = 670$

故
$$P(H = 1|X = 1) = \frac{180}{670} = 0.269$$

- 蒙提霍尔问题 (The Monty Hall Problem)

- 游戏描述

- 有三扇门，其中一扇门后面有一辆豪车。你可以有两次选门的机会，如果选中的门后面有豪车，则豪车归你；否则，空手而归

- 游戏过程

- 你先选一扇门
 - 然后主办方打开剩下的两扇门中的一扇门，但这个门后面没有豪车
 - 问题：第二次选择时，你是保留上次选择的门不变，还是选另一扇仍然关上的门

1号门

第一次选择的门

2号门

没有
豪车

3号门

是保持不变呢？

还是选择改变？

这是一个问题！

- 假定

- 你选择了1号门（后面是否有豪车不清楚）
- 主办方打开了2号门，后面没有豪车
- 你可以做第二次选择

- ✓ 继续选择1号门
- ✓ 改为选择3号门

这会是一个问题吗？

是吗？

不是吗？

- 约定

- H 表示后面有豪车的门标号的随机变量。 $H = i$ 表示第 i 扇门后有豪车。在无任何信息的情况下，各门后有豪车的概率相同（先验概率），即

$$✓ P(H = 1) = P(H = 2)P(H = 3) = 1/3$$

- X 表示主办方选择的门标号的随机变量。 $X = i$ 表示主办方选择第 i 扇门

- 任务

- 根据已知信息 $X = 2$ （主办方打开2号门），求解后验概率 $P(H|X = 2)$

- 在你选择1号门后，主办方选择打开哪号门的概率（注意：主办方事先知道豪车在哪个门后）
 - 如果豪车在1号门后，主办方可以随机选择打开2号门或3号门（这两门后都没有豪车）
 $\checkmark P(X = 2|H = 1) = P(X = 3|H = 1) = 1/2$
 - 如果豪车在2号门后，主办方只能打开3号门
 $\checkmark P(X = 2|H = 2) = 0; P(X = 3|H = 2) = 1$
 - 如果豪车在3号门后，主办方只能打开2号门
 $\checkmark P(X = 2|H = 3) = 1; P(X = 3|H = 3) = 0$
- 已知主办方打开2号门，即 $X=2$ ，利用贝叶斯公式计算如下

$$\left. \begin{aligned} P(H = 1|X = 2) &= \frac{P(X = 2|H = 1)P(H = 1)}{P(X = 2)} = \frac{1}{P(X = 2)} \times \frac{1}{2} \times \frac{1}{3} \\ P(H = 2|X = 2) &= \frac{P(X = 2|H = 2)P(H = 2)}{P(X = 2)} = \frac{1}{P(X = 2)} \times 0 \times \frac{1}{3} \\ P(H = 3|X = 2) &= \frac{P(X = 2|H = 3)P(H = 3)}{P(X = 2)} = \frac{1}{P(X = 2)} \times 1 \times \frac{1}{3} \end{aligned} \right\} P(X = 2) = \frac{1}{2} \Rightarrow \left\{ \begin{aligned} P(H = 1|X = 2) &= \frac{1}{3} \\ P(H = 2|X = 2) &= 0 \\ P(H = 3|X = 2) &= \frac{2}{3} \end{aligned} \right.$$

- 例子： $x \in \{\text{雨天}, \text{非雨天}\}$, $y \in \{\text{晴天}, \text{非晴天}\}$

$X \backslash Y$	晴天	非晴天
雨天	0.01	0.24
非雨天	0.25	0.50

$$\begin{aligned} H(X, Y) &= -0.01 \log 0.01 - 0.24 \log 0.24 - 0.25 \log 0.25 - 0.5 \log 0.5 \\ &\approx 1.08 \end{aligned}$$

- $0 \leq \mathbb{H}(X) \leq \log|\mathcal{X}| = \log S$, 当 X 服从均匀分布时, 其熵取得最大值
- $0 \leq \mathbb{H}(Y|X) \leq \mathbb{H}(Y)$
 - 如果知道 X , 我们对 Y 不确定性的认知不会增大
- $\max\{\mathbb{H}(X), \mathbb{H}(Y)\} \leq \mathbb{H}(X, Y) \leq \mathbb{H}(X) + \mathbb{H}(Y)$

约束条件： $\sum_{s=1}^S p(x_s) = 1$

带等式约束的极值问题，
可用拉格朗日乘子法求解

均匀分布时，其熵取得最大值

拉格朗日函数

$$\mathcal{L}(p(x_1), \dots, p(x_S)) = \sum_{s=1}^S p(x_s) \log p(x_s) + \lambda \left(1 - \sum_{s=1}^S p(x_s) \right)$$

拉格朗日乘子

(对每个等式约束引入一个拉格朗日乘子)

$$\frac{\partial \mathcal{L}}{\partial p(x_s)} = 0 \Rightarrow p(x_s) = \exp(\lambda - 1)$$

$$\frac{\partial \mathcal{L}}{\partial \lambda} = 0 \Rightarrow \sum_{s=1}^S p(x_s) = 1$$

$$\exp(\lambda - 1) = \frac{1}{S} \Rightarrow p(x_s) = \frac{1}{S}$$

$$\mathbb{H}(Y|X) \leq \mathbb{H}(Y)$$

$$\begin{aligned}
 \mathbb{H}(Y|X) &= - \sum_x p(x) \sum_y p(y|x) \log p(y|x) \\
 &= - \sum_y \sum_x p(x)p(y|x) \log p(y|x) \\
 &= \sum_y - \sum_x p(x)p(y|x) \log p(y|x) \\
 &\leq \sum_y -p(y) \log p(y) = \mathbb{H}(Y)

$f(u) = -u \log u$ 是上凸函数

$$f\left(\sum_i \lambda_i u_i\right) \geq \sum_i \lambda_i f(u_i) \quad \lambda_i \geq 0, \sum_i \lambda_i = 1$$

$$\lambda_x = p(x) \quad u_x = p(y|x)$$

$$f\left(\sum_x p(x)p(y|x)\right) \geq \sum_x p(x)(-p(y|x) \log p(y|x))$$

$$-p(y) \log p(y) \geq - \sum_x p(x)p(y|x) \log p(y|x)$$

$$\max\{\mathbb{H}(X), \mathbb{H}(Y)\} \leq \mathbb{H}(X, Y) \leq \mathbb{H}(X) + \mathbb{H}(Y)$$

$$\mathbb{H}(X, Y) = \mathbb{H}(X) + \mathbb{H}(Y|X) = \mathbb{H}(Y) + \mathbb{H}(X|Y)$$

$$0 \leq \mathbb{H}(Y|X), 0 \leq \mathbb{H}(X|Y)$$

$$\mathbb{H}(X) \leq \mathbb{H}(X, Y)$$

$$\mathbb{H}(Y) \leq \mathbb{H}(X, Y)$$

$$\max\{\mathbb{H}(X), \mathbb{H}(Y)\} \leq \mathbb{H}(X, Y)$$

$$\mathbb{H}(X, Y) = \mathbb{H}(X) + \mathbb{H}(Y|X)$$

- 给定随机变量 X 上的两个分布 p 和 q , 其交叉熵定义如下

– 离散型随机变量

$$\mathbb{H}(p, q) \triangleq - \sum_x p(x) \log q(x)$$

– 连续型随机变量

$$\mathbb{H}(p, q) \triangleq - \int p(x) \log q(x) dx$$

- 主要用于度量两个概率分布间的差异性信息, 当 $q = p$ 时, 交叉熵最小

$$p = \underset{q}{\operatorname{argmin}} \mathbb{H}(p, q)$$

- 也称相对熵 (relative entropy), 是两个概率分布间差异度量方法
- 给定随机变量 x 上的两个分布 p 和 q , 其KL散度定义如下

– 离散型随机变量

$$\text{KL}(p \parallel q) \triangleq \sum_x p(x) \log \frac{p(x)}{q(x)} = - \sum_x p(x) \log \frac{q(x)}{p(x)} = \mathbb{E}_{x \sim p(x)} \left[\log \frac{p(x)}{q(x)} \right]$$

– 连续型随机变量

$$\text{KL}(p \parallel q) \triangleq \int p(x) \log \frac{p(x)}{q(x)} dx = - \int p(x) \log \frac{q(x)}{p(x)} dx = \mathbb{E}_{x \sim p(x)} \left[\log \frac{p(x)}{q(x)} \right]$$

- KL散度不具有对称性, 不是距离度量

$$\text{KL}(p \parallel q) \neq \text{KL}(q \parallel p)$$

- 主要性质

- $\text{KL}(p \parallel q) \geq 0$

- 当且仅当 $p = q$ 时, $\text{KL}(p \parallel q) = 0$

- 与交叉熵的关系

$$\begin{aligned}\text{KL}(p \parallel q) &= - \sum_x p(x) \log \frac{q(x)}{p(x)} \\ &= - \sum_x p(x) \log q(x) + \sum_x p(x) \log p(x) \\ &= \mathbb{H}(p, q) - \mathbb{H}(p)\end{aligned}$$

同理，连续情况下可得出相同的结论。

$$\text{KL}(p \parallel q) \geq 0$$

$f(u) = -\log u$ 是下凸函数

Jensen不等式

$$f\left(\sum_i \lambda_i u_i\right) \leq \sum_i \lambda_i f(u_i) \quad \lambda_i \geq 0, \sum_i \lambda_i = 1$$

$$\lambda_x = p(x) \quad u_x = \frac{q(x)}{p(x)}$$

$$f\left(\sum_x p(x) \frac{q(x)}{p(x)}\right) \leq \sum_x p(x) f\left(\frac{q(x)}{p(x)}\right)$$

$$f\left(\sum_x q(x)\right) \leq \sum_x p(x) \left(-\log \frac{q(x)}{p(x)}\right) \longrightarrow 0 \leq \text{KL}(p \parallel q)$$

对连续情况，下凸函数有类似性质，同理可推出 $\text{KL}(p, q) \geq 0$

$f(u) = -\log u$ 是下凸函数

$$f\left(\int g(x)p(x)dx\right) \leq \int f(g(x))p(x)dx$$

由于 $-\log u$ 是严格下凸函数，不等式两边相等的充分必要条件 $p = q$

- 假定任务需要用相对简单分布 $q(x)$ 去近似分布 $p(x)$ ，有以下两种方法

$$-\min_q \text{KL}(p \parallel q)$$

✓ $\text{KL}(p \parallel q)$ 也称前向KL散度 (forwards KL, 常用)

$$\text{KL}(p \parallel q) \triangleq \mathbb{E}_{x \sim p(x)} \left[\log \frac{p(x)}{q(x)} \right]$$

$$-\min_q \text{KL}(q, p)$$

✓ $\text{KL}(q \parallel p)$ 也称逆向KL散度 (reverse KL)

$$\text{KL}(q \parallel p) \triangleq \mathbb{E}_{x \sim q(x)} \left[\log \frac{q(x)}{p(x)} \right]$$

蓝线为被近似的分布 $p(x)$ ，红线为近似分布 $q(x)$

为描述简洁，后续课程中， $P(X = x)$ 统一简写成 $p(x)$ 。根据上下文， x 即可以代表某个具体样本，也可以是变量，代表任意样本。
